FOREWORD

This report was prepared by Mechanical Technology Incorporated, 968 Albany-Shaker Road, Latham, New York 12110, under USAF Contract No. AF 33(615)-1895. The contract was initiated under Project No. 3145, "Dynamic Energy Conversion Technology", Task No. 314511, "Nuclear Mechanical Fower Units". The work was administered under the direction of the Air Force Aero Propulsion Laboratory, Research and Technology Division, with Mr. John L. Morris (APFL) acting as project engineer.

This report novers work conducted from 1 April 1964 to 1 April 1965.

This report was submitted by the authors for review on 18 March 1965. It is Part IV of final documentation issued in multiple parts. This report also is identified by the contractor's designation MTI-65-TR-35.

This technical report has been reviewed and is approved.

ARTHUR V. Churchill, Chief Fuels and Lubricants Branch Technical Support Division Air Force Aero Propulsion Laboratory

ABSTRACT

This Part IV of the Final Report precents design data for the stiffness characteristics of ball bearings for use in analyzing the dynamical performance of a rotor. The dynamic characteristics of fluid film bearings are given in Pert III which also gives the methods for performing the analysis of the rotor-bearing system.

Design data are presented for the extra-light and light group of deep-grooved and angular contact bearings undergoing either a pure radial load, pure axial load, or combined radial load with axial preload. The data are given in graphical form and cover both radial stiffness and load-carrying capacity. A nominal damping value for ball bearings, obtained from experimentation, is suggested.

Some of the general guide rules for the selection of ball bearings are given.

These are concerned with fatigue life, limiting speeds, design, and lubrication.

Safe load levels are indicated.

I

INTRODUCTION

The purpose of this report is to present design data for typical deep-groove and angular contact bearings of the commonly used light and extra-light series. The data may be used for various rotor-ball bearing system designs, in conjunction with our (MTI) critical speed and unbalance response programs.

The information is presented in graphical form. It consists of load carrying capacity, radial and axial stiffness, and load levels.

A complete description is given for all the variables used. A section entitled "Design Requirements" is written to describe various parameters and to present design considerations, guidelines and limitations.

A number of examples on the application of the curves to specific cases are included.

The analyses used are written in the Appendix, along with a computer program listing of the calculational procedure.

If any particular case is not covered by the included curves, more data may be generated by computer program PNO-182, IBM 1620-60K.

DESIGN REQUIREMENTS

A ball bearing schematic is shown as Fig. A to illustrate standard nomenclature.

Types of Bearings

The single row, deep groove ball bearing will sustain radial loads and in addition a substantial thrust load in either direction. When using this type of bearing, careful alignment between the shaft and housing is essential.

The angular contact ball bearing is designed to support a thrust load in one direction or a thrust load (preload) combined with a radial load. These bearings can be mounted singly or, when the side surfaces are flush ground, in multiple, either face-to-face or back-to-back for all combinations of thrust and radial loading. The basic difference between the two is the larger clearance and greater shoulder height of the angular contact bearing. Generally, this will permit operation with higher thrust loads and at higher speeds than the deep groove bearing.

Load Level

The load levels shown (C/P = 5 and C/P = 10) correspond to normally encountered Hertz Stress levels of 230,000 and 186,000 psi respectively.

Ball Bearing Damping

The only available damping information was from non-rotating tests on a grease packed ball bearing (A-2) system. The measured value was in the order of 15-20 pounds sec/in. This should be used only as a "ballpark" since it should be much higher in the rotating condition, and for larger bearing sizes.

Race Curvatures

Since the question of stiffness and rotor dynamics will be a major factor at high speeds, some design guidelines for this aspect are in order. Mormally, more open curvatures, one piece machined retainers, and generous internal clearances are preferred. The normal curvatures are 51.6 percent for inner race and 53 percent for outer. Open curvatures, for high speed range, between 54 percent and 57 percent for both inner and outer are used. The 57 percent curvature is widely used and is included in the design discussion.

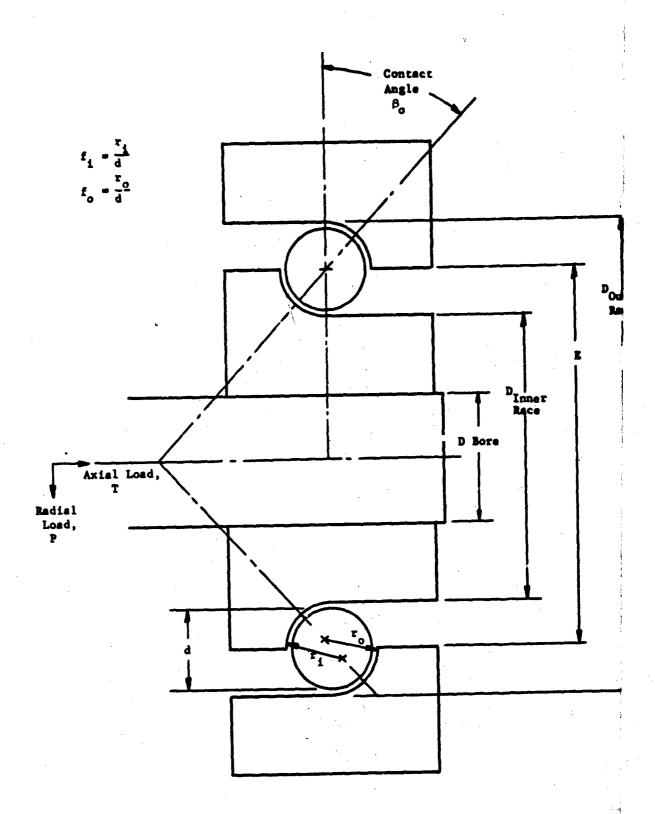

Fig. A Ball Bearing Schematic

Ball Bearings - Life

The selection of ball bearings for various applications consider such factors as load, speed, temperature, environment, design, and lubrication. However, the initial sizing and selection is usually based upon the fatigue rating of the bearing.

Based upon a statistical distribution proposed by Weibull and the analytical and experimental work of Lundberg and Palmgren the life of the bearing for a given probability of survival has been found to vary inversely as the cube of the applied radial load. For other than radial loading, an equivalent radial load is defined. A Specific Dynamic Capacity (C) is defined as that radial load which will result in a life of one million inner race revolutions with a 90 percent probability of survival. The AFRMA (Anti Friction Bearing Manufacturers Association) has standardized on the following formula for (C):

$$C = f_c (i \cos \beta_0)^{0.7 + 2/3} d^{1.8}$$
 (1)

where i = the number of rows of balls in any one bearing

= the number of balls per row

 β_0 = the angle of contact

d = the ball diameter, inch

 f_c = a factor depending on oscillation and material

For normal bearing proportions $f_{\rm C}\approx 4500$. The life (90 percent probability of survival) at any other radial load or equivalent radial load (P) is related to the Specific Dynamic Capacity (C) as follows:

$$L = (C/P)^{\frac{2}{3}}$$
 millions of inner race revolutions (2)

It is normally assumed that speed affects life in a linear fashion; that is, life varies inversely with speed. *For a given operating speed of N rpm, the number of revolutions which correspond to H hours of life is

L = 60 NH revolutions

Based upon experimental data, equation (3) is too conservative at high speeds.

and

$$\left(\frac{C}{P}\right)^3 \times 10^6 = 60 \text{ NH}$$

$$H = \frac{(C/P)^3 \times 10^6}{60 \text{ N}}, \text{ hour}$$
 (3)

Catalog ratings are generated in this fashion, usually for some given number of hours of life with a 90 percent probability of survival. Five hundred hours is a common catalog rating. Note that a rating at 33-1/3 rpm for 500 hours is the Specific Dynamic Capacity.

Since this is available in the catalogs of most of the bearing companies, no further explanation of this aspect is included in this report.

Bearing Centrifugal Loading

In some instances, it is desired to estimate the life of a ball bearing at extremely high speed with little or no externally applied loading. In this case, the fatigue life is determined by the centrifugal loading of the balls on the outer ring. (Ref. 4)

The outer ring capacity is given by

$$c_o = A \left(\frac{2f_o}{2f_o - 1}\right)^{0.41} \frac{(1+\gamma)^{1.39}}{(1-\gamma)^{1/3}} \gamma^{.3} d^{1.8} z^{-1/3}$$
 (4)

where

A = material constant, usually 7140

f = outer race curvature factor (ratio curvature radius to ball diameter)

7 = ball diameter to pitch diameter ratio, d/E

d = ball diameter - inch/

Z = number of balls

E = pitch diameter - inch

The life of the outer ring is given as

$$(c_0/P_{c.f.})^3 = 90\%$$
 life in 10^6 revs. (5)

where

$$P_{c.f.} = centrifugal ball loading$$

$$P_{c.f.} = 5.257 \times 10^{-7} d^3 EN_i^2 (1-7)^2$$

Effects of Cyclic Loading on Bearing Life

As was previously shown, the fatigue life of a rolling element bearing is defined in terms of a 90 parcent probability of survival. A specific dynamic capacity C is defined as that radial load which will result in a life of 10⁶ inner race revolutions with 90 percent survival probability. The 90 percent life at any other load P is related to the specific dynamic capacity as follows:

$$L = (C/P)^3 10^6 \text{ Rev}.$$
 (2)

When the load varies in a series of known steps, some equivalent or mean load is defined as follows:

$$P_{m} = \left(\frac{P_{1}^{3} N_{1} + P_{2}^{3} N_{2} - \cdots + P_{n}^{3} N_{n}}{N_{1} + N_{2} - \cdots + N_{n}}\right)^{\frac{1}{3}}$$
(6)

where P_1 , P_2 , P_n are loads applied for N_1 , N_2 , N_n cycles.

For the case of vibratory loading, an integral form of Equation (6) can be used:

$$P_{m} = \left(\frac{1}{N} \int P^{3} dN\right)^{1/3} \tag{7}$$

In the general case, the loading will consist of some steady load \mathbf{P}_0 and a sinusoidal load \mathbf{P}_1 sin ωt .

The bearing loading P is given as

$$P = P_0 + P_1 \sin \omega t \tag{8}$$

Using this in Equation (7) yields the following:

$$P_{m} = \left[\frac{1}{\pi} \int_{0}^{\pi} (P_{o} + P_{1} \sin \omega t)^{3} d(\omega t)\right]^{1/3}$$
 (9)

Expansion of Equation (9) gives

$$P_{m} = \left[\frac{1}{\pi} \int_{0}^{\pi} (P_{o}^{3} + 3P_{o}^{2}P_{1} \sin \omega t (+ 3P_{o}P_{1}^{2} \sin^{2} \omega t + P_{1}^{3} \sin^{3} \omega t) d \omega t)\right]^{1/3}$$
(10)

$$P_{m} = \left[\frac{1}{\pi} \left(P_{0}^{3} \omega t - 3 P_{0}^{2} P_{1} \cos \omega t + 3 P_{0}^{2} P_{1}^{2} \frac{\omega t}{2} \right) - 3 P_{0}^{2} P_{1}^{2} \frac{\sin 2\omega t}{4} - P_{1}^{3} \cos \omega t + P_{1}^{3} \frac{\cos^{3} \omega t}{3} \right]^{1/3}$$

$$P_{m} = \left[\frac{1}{\pi} \left(P_{o}^{3}\pi + \frac{3}{2} P_{o}^{2}P_{1}^{2}\pi\right)\right]^{1/3}$$

$$= \left[P_{o}^{3} \left(1 + \frac{3}{2} \frac{P_{1}^{2}}{\tilde{P}_{o}^{2}}\right)\right]^{1/3}$$
(11)

$$\frac{P_{m}}{P_{o}} = \left[1 + \frac{3}{2} \left(\frac{P_{1}}{P_{o}}\right)^{2}\right]^{1/3} \tag{12}$$

The results of Equation (12) are plotted in Figure B as a function of the cyclic load ratio.

The life may be found from Equation (2) using the equivalent load $P_{\rm m}$.

Often the steady state load P_0 is known and the effect of various cyclic loads is desired. The life due to the steady state load P_0 is

$$L_o = (C/P_o)^3 \tag{13}$$

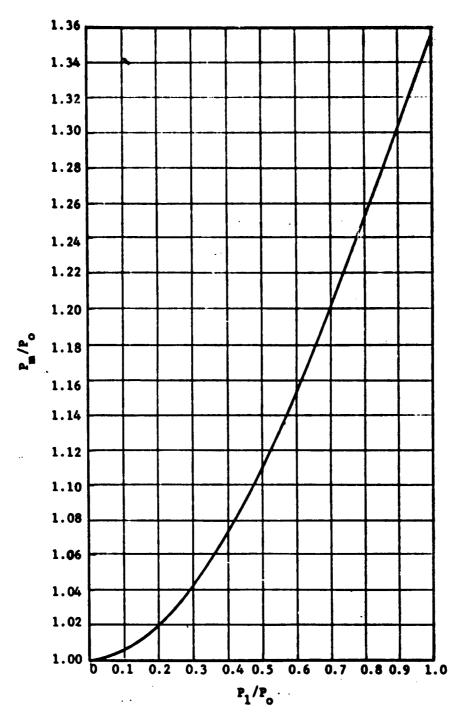

Fig. B Equivalent Load Ratio as a Function of Cyclic Load Ratio

8

While the life due to the equivalent load P is

$$L = (C/P_m)^3 \tag{14}$$

The ratio of the lives is

$$\frac{L}{L_o} = \frac{(C/P_m)^3}{(C/P_o)^3} = \left(\frac{1}{P_m/P_o}\right)^3$$
 (15)

The life ratio as a function of the equivalent load ratio is shown in Figure C.

In summary, the results apply to the following:

- 1. $P_1 \leq P_0$
 - 2. Radial Loading
 - 3. P is unidirectional
 - 4. P₁ is the single amplitude of the cyclic disturbance.

The above can be used with manufacturers' catalog data by roting that these are set up for some given life (usually 500 hours) at various speeds. The corresponding load is tabulated.

The case where a cyclic load only is applied is sometimes encountered. The bearing load is then

$$P = P_1 \sin \omega t \tag{16}$$

Equation (7) now becomes

$$P_{m} = \left[\frac{1}{\pi} \int_{0}^{\pi} (P_{1} \sin \omega t)^{3} d(\omega t)\right]^{1/3}$$

$$= \left[\frac{1}{\pi} P_{1}^{3} (-\cos \omega t + \frac{1}{3} \cos^{3} \omega t)_{o}^{\pi}\right]^{1/3}$$

$$= 0.752 P_{1}$$
(17)

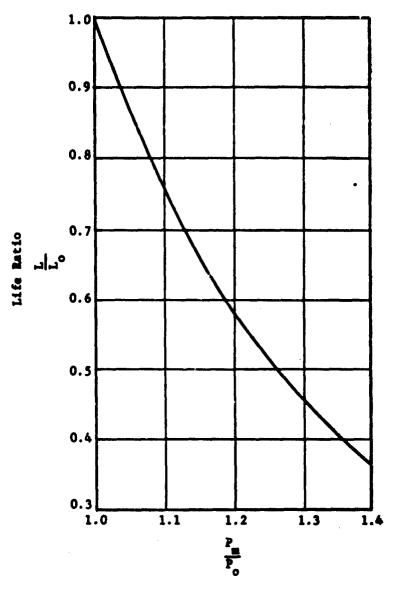

Fig. C Bearing Life Ratio As A Function of Equivalent Load Ratio

The ratio of equivalent loading to the single amplitude of the cyclic loading is

$$\frac{P_{m}}{P_{1}} = 0.752 \tag{18}$$

Bearing life is determined from P.

As was previously noted, Equation (12) and Figure-8 were derived for radial loading. However, the relations can be adapted for use with thrust loads, if the thrust load is represented by

$$T = T_0 + T_1 \sin \omega t , \qquad (19)$$

where T_0 is the steady thrust load and T_1 is the single amplitude of the cyclic thrust loading. This gives a similar relation to Equation (12) as follows:

$$\frac{T_{m}}{T_{o}} = \left[1 + \frac{3}{2} \left(\frac{T_{1}}{T_{o}}\right)^{2}\right]^{1/3} \tag{20}$$

Figure B can be used to obtain either a mean radial or thrust load. However, in the case of thrust loading, bearing life must be calculated using an equivalent radial load with the specific dynamic capacity. For calculation purposes (preliminary engineering calculations) the equivalent radial load is given by:

Equiv. Rad. Load =
$$0.37 P + 2T$$
 (21)

where P is the radial load and T is the thrust load. Either T or P, or both are replaced by P_m and T_m where cyclic loading is involved. More accurate relationships for the various bearing types are found in the manufacturers' catalogs or the AFBMA standards.

Lubricant Life

In many instances, fatigue life is not the major consideration since the loading is light. The lubricant is usually the limiting item insofar as life is concerned. The first consideration is to be sure that lubricant and the lubrication system are adequate for the speed range.

Unfortunately, there are no exact guiderules that can be set. However, some generalizations are possible with respect to normal applications.

System	Speed Limit [x N (bore in m x spee	d in RPH)
Grease	250,000	(ribbon retainer)	
Oil Level	300,000	(ribbon retainer)	_
Mist ·	700,000	(machined retainer)	
Jet 011	>10 ⁶ ,	(machined retainer)	200

Above 300,000 dN, the usual ribbon retainer would be replaced by a machined retainer of metal or phenolic. For normal temperatures, the phenolic retainer is commonly used. With special greases, retainer design, and light loading, grease lubrication has been used to speeds of 750,000 dN.

With respect to grease lubrication, there is evidence that life is reduced in some logarithmic fashion with increasing dN value. This is similar to the effect of temperature. Figure D shows a typical behavior of life with respect to temperature. A reasonable rule of thumb is that life is cut in half for each 10°C rise over 100°C.

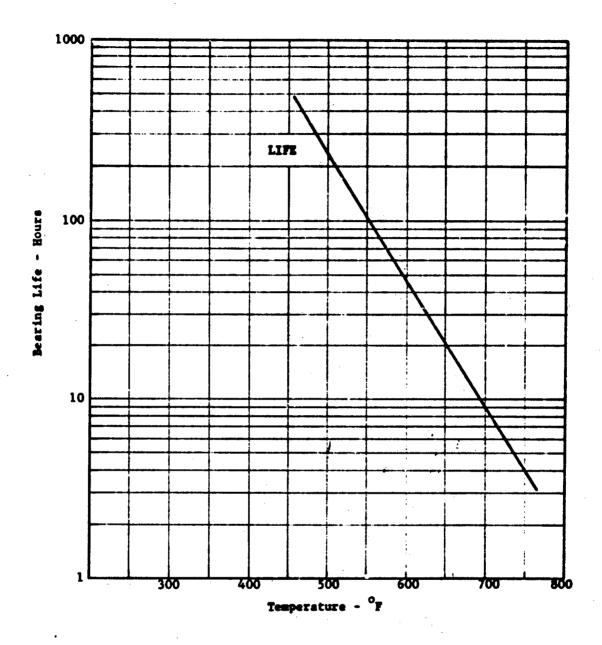

Fig. D Bearing Life Versus Temperature

III

DESIGN DATA

Description and Discussion of Charts

There are basically three separate sets of design charts included in this report, namely:

- a. Pure Radial Loaded Bearings (Deep Groove) Contact Angle $\beta_{\alpha}=0^{\circ}$
- b, Pure Thrust Loaded Bearings (Deep Groove) Contact Angle $\beta_0 = 10^{\circ}$
- c. Angular Contact Bearings with Axial Preload and Applied Radial Load $\beta_{_{\rm C}}=25^{\rm O},~15^{\rm O}$

Table I describes the dimensions and symbols used for the deep-grooved ball bearings. Table II contains information pertaining to the angular contact bearings.

The first set of four charts contains graphs of radial stiffness versus radial load. Load levels are indicated on the curves. The effects of bearing size and race curvatures are illustrated by these four charts. In general, a bearing with tighter raceway curvatures is a stiffar bearing. For example, a bearing with curvatures of $f_i = .516$, $f_o = .530$ is stiffer than the same bearing operating with curvatures of $f_i = f_o = .570$, for the same radial load. Radial stiffness is higher for a bearing with a larger bore diameter and/or a greater number of balls. Note, for pure radial load, the linear relationship between log S_R and log P.

The second set of eight charts contains graphs of axial stiffness and axial deflection versus axial thrust applied load. Load levels are tabulated in Table III for these particular bearings undergoing a pure thrust load since cross plots of C/P will add confusion when reading the curves. Deflection curves are included to aid in analyzing a double acting thrust bearing set. The deflection curve for a double acting thrust bearing set is constructed from the deflection curve of a single bearing by adding increments of deflection to one bearing and subtracting from the other. The corresponding load differences equal the externally applied load. A similar observation, as given

above for radially loaded bearings, can be made for the thrust loaded bearing, is a hearing operating with curvatures of $f_1 = .516$, $f_0 = .530$ is stiffer than the same bearing operating with curvatures of $f_1 = f_0 = .570$, for the same axial load. For all practical purposes, however, an average curve may be drawn for axial stiffness versus axial load for all bearing sizes. In particular, the bearing with the smaller bore and less bells is less stiff at light loads and more stiff at heavy loads as compared to the larger bore bearing. There is an approximate linear relationship between log S_{\perp} and log T.

The third set of (24) charts contain graphs of radial stiffness versus radial load. Load levels are indicated on the curves. The effects of bearing size, race curvatures, initial contact angle, and axial preload are illustrated by these 24 charts. For the same radial load and axial preload, a bearing operati with curvatures of $f_i = .516$, $f_o = .530$ is stiffer than the same bearing operat with curvatures of $f_i = f_0 = .570$. The radial stiffness level is higher for a bearing with a larger bore diameter and/or a greater number of halis, and the smaller initial contact angle. $(\beta_0 = 15^{\circ})$. In general, the radial stiffnessradial load curve for an angular contact bearing is composed of three different behaving regions. One region shows the stiffness to be constant with varying radial load. (This is the light radial load region.) The middle, or moderate radial load region shows a minimum value for radial stiffness. The heavily radial loaded region shows a linear relationship between log S_p and log P. Th: third region is similar in behavior to that of the characteristics of a pure re loaded deep grooved bearing. The basic cause for this curve having three sepat regions is due to the axial preload. In region one, the axial preload has a great effect in holding the radial stiffness constant. In region two, where the applied radial load becomes equal in magnitude to the axial preload, the radial stiffness tends to decrease with increasing applied radial load to a minimum value. In the third region, the axial preload has little or no effect, and the angular contact bearing reflects the behavior of a pure radially loaded bearis i.e., a linear $\log S_p$ versus $\log P$ relationship.

Thus another point one is led to observe is the role of axial preload magnitude on the three regions of a typical stiffness versus load curve. Three different preloads are represented in these charts and are tabulated in Table II. These

preloads are given the names selected light, moderate, and preferred heavy. The effect of increased preload is to increase the region one load range and decrease region three load range. Thus, the ultimate is a constant radial stiffness with varying radial load obtained with an infinite preload. The increased preload also has the effect of increasing the level of stiffness in regions one and two. However, it should be noted particularly that the level of stiffness in region three, for the same radial load, is the same for all preload values. This, as mentioned above, is because the axial preload effect is relieved entirely above a certain (radial load)(axial preload) ratio. (Approximately P/T = 3 for $\beta_0 = 25^\circ$ and R/T = 4 for $\beta_0 = 13^\circ$.)

In general, the light and extra light deep grooved bell bearings examined here will have a radial stiffness ranging from 10^5 to 2×10^6 for radial loads of from 10 to 2,000 lbs. The angular contact bearings will have radial stiffness values from 2×10^5 to 2×10^6 for radial loads of from 10 to 2,000 lbs. The deep grooved ball bearings will have an axial stiffness per bearing of from 2×10^4 to 4×10^6 for thrust loads of from 10 to 10^4 lbs. As in the case of the preloaded radial bearing, preloading will increase these values of axial stiffness.

SAMPLE PROBLEMS TO ILLUSTRATE USE OF DESIGN CHARTS

Four particular examples are included in this section:

- 1. Pure Radial Loaded Bearing
- 2. Unidirectional Thrust Loaded Bearing
- 3. Double-Acting Thrust Loaded Bearing
- 4. Radial Loaded, Axial Preloaded Angular Contact Bearing

1. Pure Radial Loaded Bearing

What are the radial stiffness values corresponding to radial loads of 100 and 700 pounds for a deep-grooved ball bearing with a BORE = 5906 inch and $f_1 = f_0 = .570$?

From Table 1, this bearing corresponds to A2.

From Figure 2:

Radial Load (1b) Radial Stiffness (1b/in)

100 2.88 x 10⁵

700 5.55 x 10⁵

2. Unidirectional Thrust Loaded Bearing

What are the axial stiffness values corresponding to axial loads of 100 and 700 pounds for the same deep-grooved ball bearing as used in sample problem 1, above?

From Figure 7:

Thrust Load (1b) Thrust Stiffness (1b/in)

100 9.10 x 10⁴

700 3.22 x 10⁵

3. Double-Acting Thrust Loaded Bearing

What is the axial stiffness for a double-acting, deep-grooved ball bearing, thrust bearing set, preloaded to 200 pounds? The bearings are type A-2.

From Figure 8: Read off loads corresponding to equal deflections around preload of 200 pounds.

'nus,

The axial stiffness is
$$S_A = \frac{\triangle L}{5} = \frac{240 - 160}{.3 \times 10^{-3}}$$

$$S_A = 267,000 \text{ ib/in}$$

This problem may also be solved using Figure 7 in conjunction with Figure 8.

Thus,

Load (1b) Deflection (in) Stiffness (1b/in)
160
$$2.8 \times 10^{-3}$$
 1.22×10^{5}
200 3.1×10^{-3} 1.4×10^{5}
240 3.4×10^{-3} 1.58×10^{5}

$$S_A = \Sigma S = (1.58 + 1.22) \times 10^5 = 2.8 \times 10^5 \text{ lb/in}$$

or $S_A = 2 \times 1.4 \times 10^5 = 2.8 \times 10^5 \text{ lb/in}$

For light loads, i.e., loads less than the axial preload, the load-deflection characteristics are essentially linear.

4. Radial Loaded, Axial Preloaded Angular Contact Bearing

What are the radial stiffness values corresponding to radial loads of 100 and 700 pounds for an angular contact bearing with a BORE = .5906 inch and $f_i = f_o = .570$. The contact angle is 15 degrees, and it has a medium axial preload.

From Table 2, this bearing corresponds to PA 2.

From Figure 30,

Radial Load (1b)

Radial Stiffness (lb/in)

100

 4.45×10^5

700

5.90 x 10⁵

Note: One must be careful in using the charts, in particular for the angular contact bearing, that the design contact angle and axial preloading design value correspond to the values given in the Figure legend.

APPENDIX

A. Analysis

The theory used for predicting the load carrying capacity, deflections, and stresses of deep-grooved, and angular contact bearings is that of Reference 1.*

The equations relating load and deflection were differentiated to obtain the equation for stiffness.

A calculational procedure was devised for predicting the maximum ball load, deflection, stiffness, and inner and outer race stresses, as a function of total applied load, preload and bearing geometry. This procedure was programmed as computer program PNO182, IBM 1620-60K.

Three separate cases are treated:

- 1) Pure Radial Load, deep grooved bearing (Ref. 2,3)
- 2) Pure Thrust Load, deep grooved bearing
- Combined Radial Load with Axial Preload, angular contact bearing (Ref. 2,3)

Pure Radial Load

Maximum Ball Load, P

$$P_0 = 4.37 * P/n$$
 A-1

Radial Deflection, 8 N

$$\delta_{N} = C_{O} P_{O}^{2/3}$$

where

$$c_0 = 7.8107 \times 10^{-6} (cb_0 + cb_1)/d^{-1/3}$$

and

$$Cb_{o} : Cb_{i} = f(f_{i}, f_{o}, E, d, \beta_{o})$$
 A-4

See Reference: Section

Radial Stiffness, SR

$$S_R = 3/2 P/\delta_N$$

A-5

Compressive Stresses, So, Si

$$s_{m} = f_{sm}(15079) \left(\frac{P_{o}}{d^{2}}\right)^{1/3}$$

A-6

where $f_{am} = f(f_i, f_o, E, d, \beta_o)$

A-7

and m = 1, or o.

Pure Thrust Load

Maximum Ball Load, P

$$P_0 = \frac{T}{n \sin \beta_1}$$

A-8

Axial Deflection, 8

$$\delta_{\rm H} = Bd + \frac{\sin (\beta_1 - \beta_0')}{\cos \beta_1}$$

A-9

where

$$B = f_i + f_0 - 1$$

A-10

and

 $\boldsymbol{\beta}_1$ is found by an iteration scheme, written below.

Applied Thrust (Axial) Load, T

$$T = nd^{2}K \cdot \sin \beta_{1} \left(\frac{\cos \beta_{0}^{\prime}}{\cos \beta_{1}} - 1 \right)^{3/2}$$

A-11

where

$$K = \left[\frac{8 \times 10^{+6}}{7.8107(cb_0 + cb_1)} \right]^{3/2}$$

A-12

and

 β_1 is found as follows:

Define the following quantities:

$$\frac{T}{nd^2} = b \qquad \cos \beta_0 = a \qquad \cos \beta_1 = x$$

Then Equation (A-11) may be written as

$$(1 - x^2)^{1/3} (\frac{a}{x} - 1) = b$$

Let
$$y = \frac{a}{x} - 1$$
, $A-13$

Then
$$y = b(1 - x^2)^{-1/3}$$

It is a known fact that $h \ll 1$. Therefore, as a good guess to start the iteration scheme for solving (A-14), let

$$y = by_1 + b^2y_2 + \dots$$
 A-15

where

$$y_1 = 1 + \frac{a^2}{3}$$

and

$$y_2 = \frac{2}{3} a^2 y_1$$
 . A-16

The procedure is:

- 1) Calculate y_1 , y_2 from (A-16) and y from (A-15), knowing a and b.
- 2) Calculate x from (a-13) knowing y.
- 3) Calculate y from (A-14).
- 4) Check y from step (3) with y from step (2).
- 5) If the values are equal

$$\beta_1 = \cos^{-1}(x),$$

otherwise use an average value for y and repeat steps (2) through (5) until agreement is obtained.

Axial Stiffness,
$$S_A$$

$$S_A = \frac{B}{nd_BK} * \left\{ \frac{3}{2} \sin^2 \beta_1 \left[\frac{\cos \beta_0'}{\cos \beta_1} - 1 \right]^{1/2} + \frac{\cos^3 \beta_1}{\cos \beta_0'} \left[\frac{\cos \beta_0}{\cos \beta_1'} - 1 \right]^{3/2} \right\} A-17$$

Compressive Stresses, So, Si

$$S_{m} = f_{sm} (15079) \left(\frac{P_{o}}{d^{2}}\right)^{1/3}$$
 A-6

where

$$f_{sm} = f(f_1, f_0, E, d, \beta_1)$$
 A-7

m = i, or o

and

P is calculated from (A-8)

Combined Radial Load and Axial Preload

The same procedure for finding β_1 as applied in the pure thrust load case is applied in this case in order to find δ_H . A value of radial deflection, δ_V , is assumed, then the radial force, ΣV , is calculated as a function of δ_H and δ_V .

The following definitions are written:

$$k' = \frac{\delta_V}{Bd}$$
 , $h' = \frac{\delta_H}{Bd}$ and

$$\phi' = \cos^{-1} \frac{\left[1 - (\sin \beta_0' + h')^2\right]^2 - \cos \beta_0'}{k'}$$
, $\cos \phi' > -1$

$$\phi' = \pi$$
, $\cos \phi < -1$

Maximum Ball Load,
$$P_0$$

$$P_0 = Kd \left[\sqrt{\left(\sin \beta_0' + h'\right)^2 + \left(\cos \beta_0' + k' \cos \phi\right)^2} - 1 \right]^{3/2}$$

$$A-19$$

where $\phi = 0^{\circ}$

Radial Deflection, $\delta_{_{\mathbf{U}}}$; Axial Deflection, $\delta_{_{\mathbf{U}}}$

$$\delta_{v} = k' Bd$$

$$\delta_{V} = k' Bd$$
 $\delta_{H} = h' Bd$

K-20

Axial Preload, T

Calculate from (A-11) and (A-12).

Radial Load, DV

$$\Sigma V = \text{nd}^{2} K \frac{1}{\pi} \int_{\phi}^{\phi} Ad\phi$$

where
$$A = \frac{\left[\sqrt{(\sin \beta_{o}^{'} + h^{'})^{2} + (\cos \beta_{o}^{'} + K^{'} \cos \phi)^{2} - 1}\right]^{3/2}}{\left[(\sin \beta_{o}^{'} + h^{'})^{2} + (\cos \beta_{o}^{'} + k^{'} \cos \phi)^{2}\right]^{1/2}}$$

and

A-21

Radial Stiffness,
$$S_R$$

$$S_R = \frac{B}{\text{nd } K} * \frac{1}{\pi} \int_{\phi}^{\phi} A \begin{cases} \frac{\cos \phi}{(\cos \beta_0^! + k^! \cos \phi)} + \frac{1}{\pi} \int_{\phi}^{\phi} A (\cos \beta_0^! + k^! \cos \phi) \end{cases}$$

$$A \left[\frac{\frac{1}{2} \left[\left(\sin \beta_{o}^{1} + h^{1} \right)^{2} + \left(\cos \beta_{o}^{1} + k^{1} \cos \phi \right)^{2} \right]^{1/2} + 1}{\left[\left(\sin \beta_{o}^{1} + h^{1} \right)^{2} + \left(\cos \beta_{o}^{1} + k^{1} \cos \phi \right)^{2} - 1 \right]^{5/2} \left[\left(\sin \beta_{o}^{1} + h^{1} \right)^{2} + \left(\cos \beta_{o}^{1} + k^{1} \cos \phi \right)^{2} \right]^{1/2}} \right]^{d\phi}} A-22$$

Compressive Stresses, So, Si

$$S_{m} = f_{sm}(15079) \left(\frac{P_{o}}{d}\right)^{1/3}$$

A-6

Where

$$f_{sm} = f(f_1, f_0, E, d, \beta_1)$$

A-7

m = i, or o, and P_o is calculated from (A-19).

B. Computer Program

A Fortran II computer program listing is included in this memorandum.

The Input Format written below should be followed when using this program, PNO182 IBM 1620-60K.

Input Format

Card 1 Identification Card

Anything may be punched in columns 2-72.

Card 2 (6 F10. 6, 314)

Item

- 1. BORE, Bore diameter, in.
- 2. ØD, Extreme outer diameter, in.
- 3. DB, Ball diameter, in.
- 4. FI, Radius of Curvature of Inner Race
- 5. FØ, Radius of Curvature of Outer .ace
- 6. BETA, Contact Angle, deg ($\beta = 0^{\circ}$ for pure radial load)
- 7. N. Total number of balls
- 8. IND, An indicator used to specify either one of three different types of calculations.

IND: O Pure Radial Load

IND: 1 Pure Thrust Load

IND: >2 Combined Radial Load - Axial Preload

9. LC, An indicator used to stop calculation procedure

LC: O Program returns to Card 1 for more input.

LC: 1 Program stops after computation is completed

Card 3 (3F10.6, 15)

IND = 0

Item

- 1. RI, Initial Radial Load, 1b.
- 2. RD, Radial Load Increment, 1b
- 3. RF, Final Radial Load, lb. (Not used in calculation. RF = 0.0)
- 4. M, Total number of radial loads

IND = 1

Item

- 1. TI, Initial Thrust Load, 1b
- 2. TD, Thrust Load Increments, 1b
- 3. CØNV, A radius of convergence used in the iteration process for calculating β_1 . CØNV = .0005 is a typical value.
- 4. M, Total number of thrust loads

IND > 2

Item

- 1. TI, Axial Preload, 1b
- 2. TD, Axial Preload Increment, 1b (Not used in calculation 7 = 0.0)
- 3. CØNV, a radius of convergence used in the iteration process for calculating $\boldsymbol{\beta}_1$.
- 4. M, Total number of preloads (must be set equal to one; i.e. H = 1)

Note: The total number of radial loads which will be calculated as a function of axial preload and radial deflection is equal to the value of IND. Thus, IND = 20, the calculational procedure will solve for '20' consecutive radial loads. A maximum of IND = 24 is allowed.

Output Format

The output is self explanatory. All linear dimensions are in inches. All loads are in pounds. The stiffness units are in 1b/in. The stresses are measured in psi.

INSTRUCTIONS

- i. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organisation (corporate author) issuing the report.
- 2a. REPORT SECURITY CLASSIFICATION: Enter the everall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.
- 25. GROUP: Automatic downgrading is specified in DeD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.
- 3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified if a meaningful title cannot be selected without classification, show title classification in all capitals in perenthesis immediately following the title.
- 4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annuil, or final. Give the inclusive dates when a specific reporting period is covered.
- 5. AUTHOR(8): Enter the name(s) of author(s) as shown en or in the report. Enter last name, first name, middle initial. If military, show rank and brench of service. The name of the principal author is an absolute minimum requirement.
- 6. REPORT DATE: Enter the date of the report as day, month, year; or month, year if more than one date appears on the report, use date of publication.
- 7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.
- 76. NUMBER OF REFERENCES. Enter the total number of references cited in the report.
- Sa. CONTRACT: OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.
- 85, &c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.
- 9a. ORIGINATOR'S REPORT NUMBER(5): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.
- 94. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers (either by the originater or by the apencor), also enter this number(s).
- 10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those

imposed by security classification, using standard statements such as:

- (1) "Qualified requesters may obtain copies of this report from DDC."
- (2) "Foreign announcement and dissemination of this report by DDC is not authorized."
- (3) "U. S. Government agencies may obtain capies of this report directly from DDC. Other qualified DDC users shall request through
- (4) "U. S. military agrecies may obtain capies of this report directly from DDC. Other qualified users shall request through
- (5) "All distribution of this report is controlled. Qualified DDC users shall request through

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

- IL SUPPLEMENTARY NOTER: Use for additional emplementary notes.
- 12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory speasoring (paying for) the research and development. Include address.
- 13. ABSTRACT: Enter an obstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation about shall be attacked.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military occurity missification of the information in the paragraph, represented as (72), (5), (6), or (9).

There is no limitation on the length of the obstruct. However, the suggested length is from 150 to 225 words.

14. REY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be solicated so that no security classification is required. Identifiers, such as equipment model designation, trade same, military project code name, grographic location, may be used as bey words but will be followed by an indication of technical content. The assignment of links, rules, and weights is optional.
